# Outline

- The Argo network and the RAPID array
  - Estimating the ocean state and velocity from satellite and Argo data
- Heat budget calculation
  - Estimating surface freshwater loss from N. Atlantic heat budget
- Freshwater budget calculation
- Implications for SSS observation

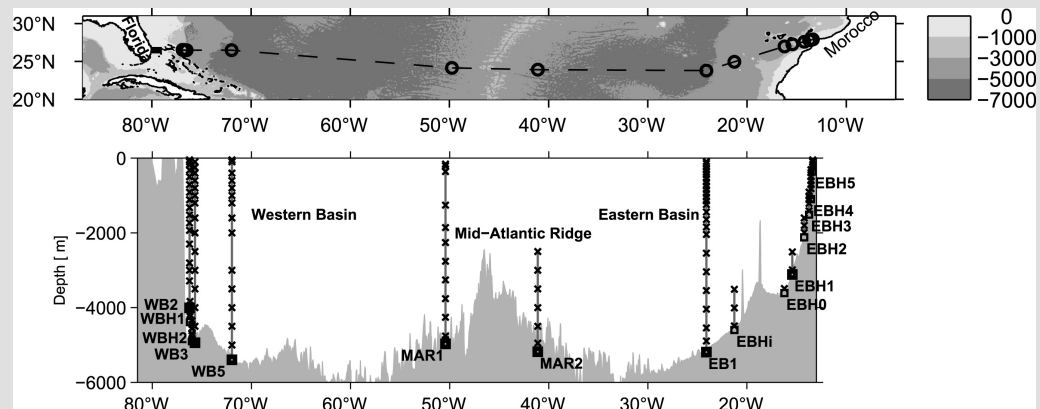

# North Atlantic Heat/Freshwater budget

# North Atlantic overturning observations

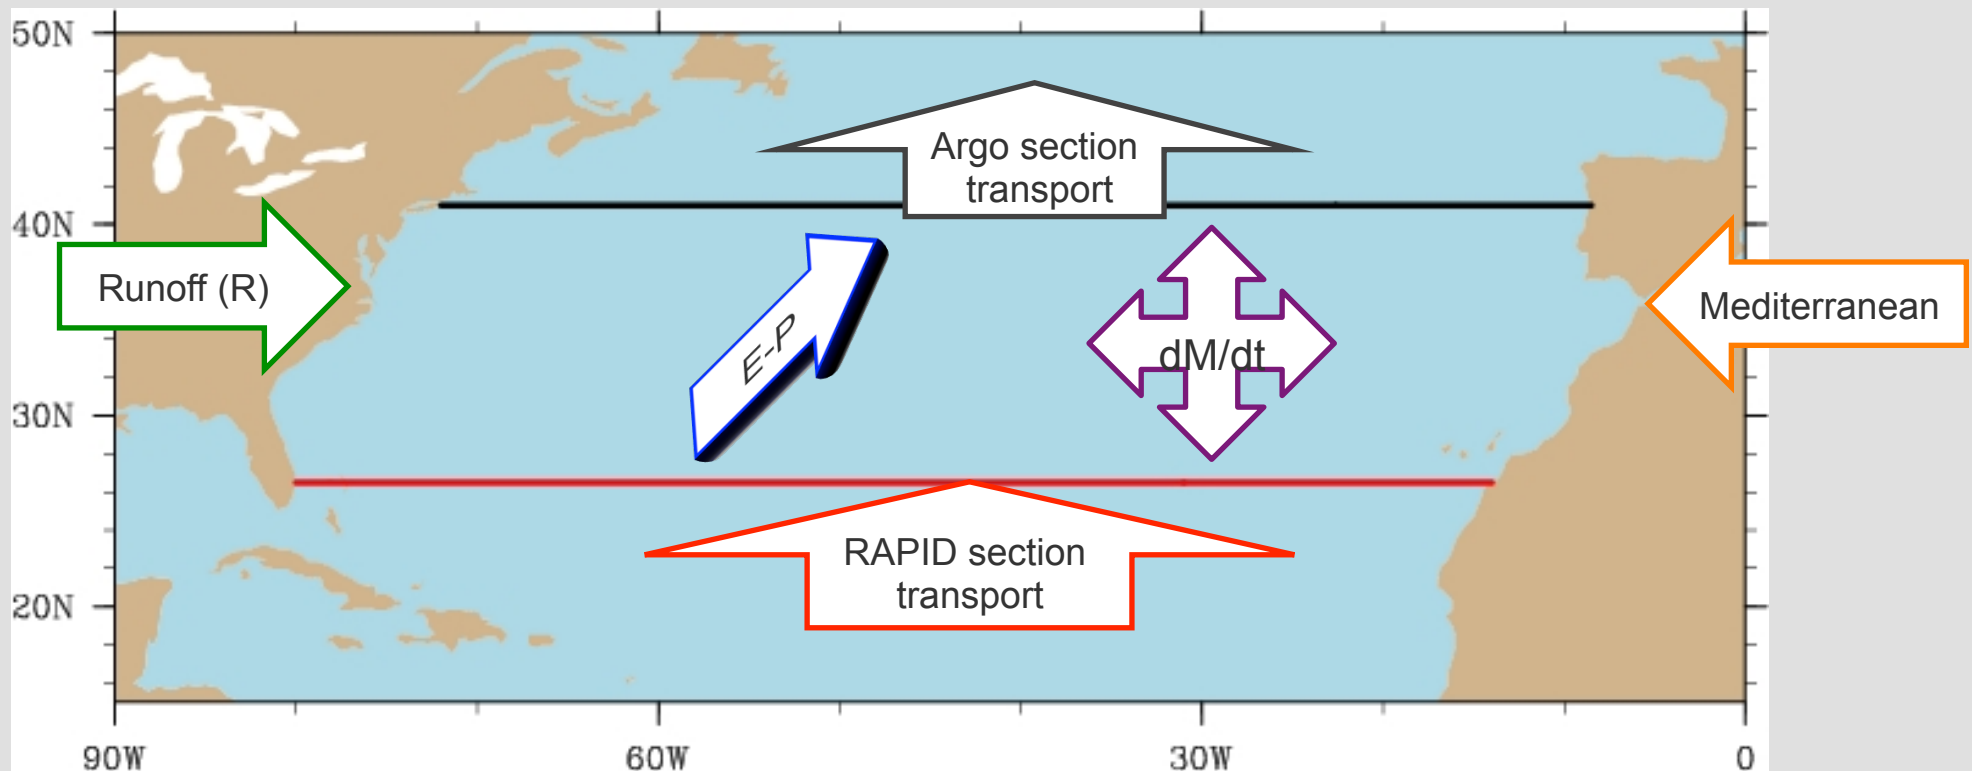

Argo/SSH network

RAPID array

# RAPID-ARGO freshwater & heat balance

$$E - P = R + \text{FWtrans}_{26.5} + \text{FWtrans}_{41} + \text{FWtrans}_{\text{Med}} + dM_{\text{FW}}/dt$$

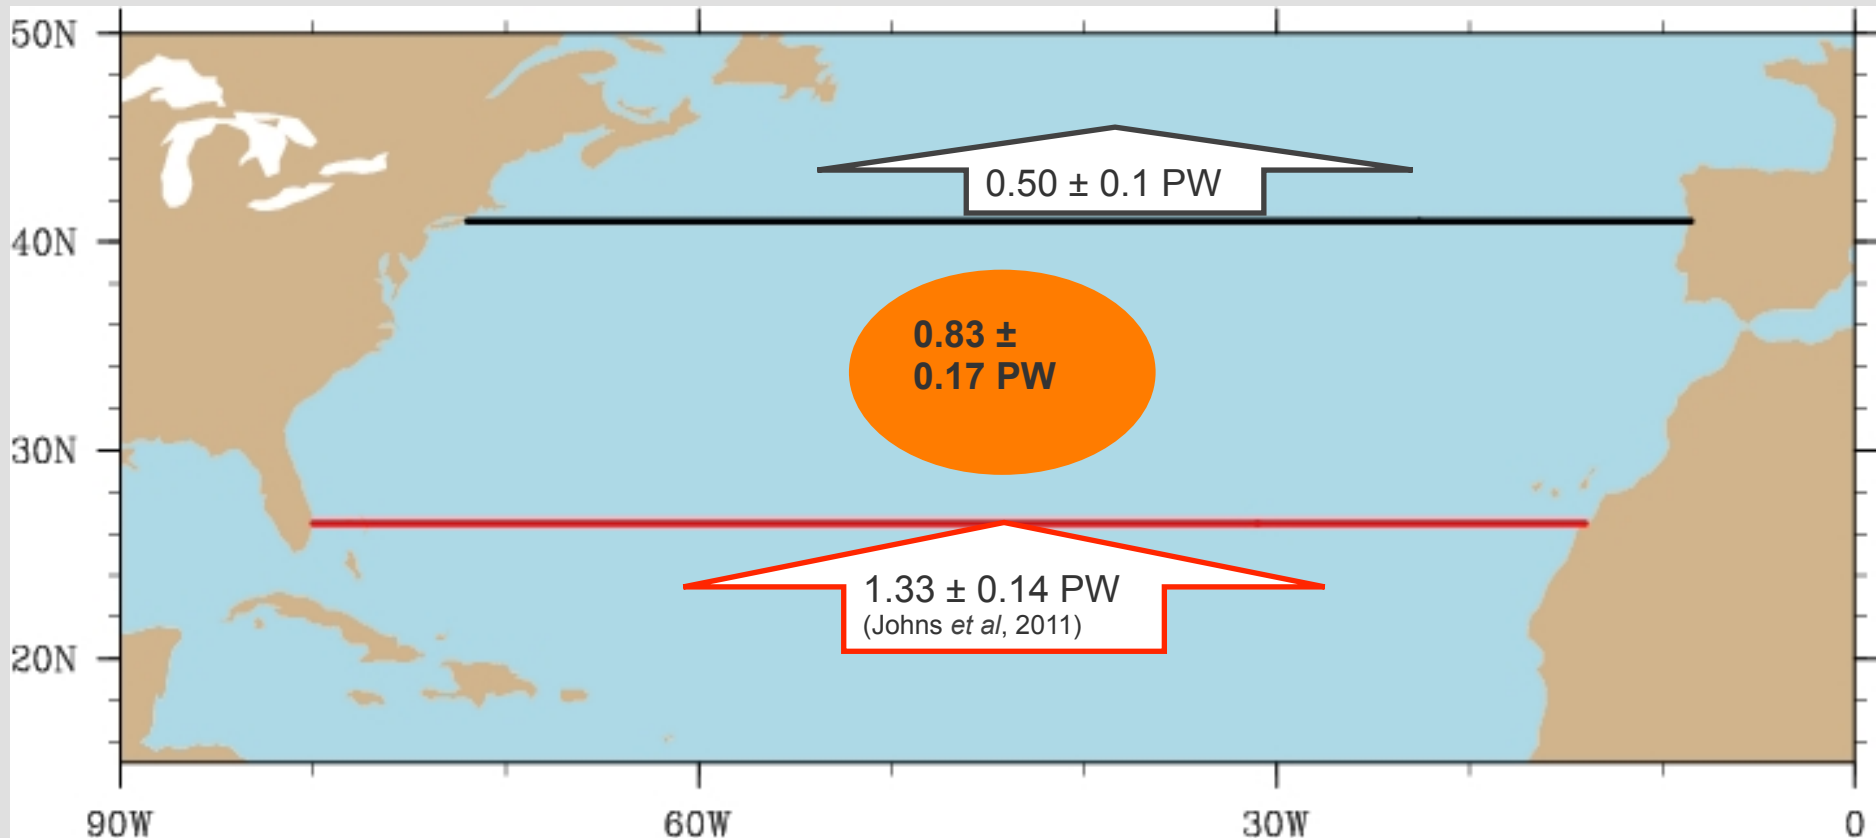

# RAPID-ARGO

## domain heat balance

$dH/dt = 0.01 \text{ PW}$  (from Roemmich & Gilson Argo data)

→ Net surface flux = 0.82 PW

# Estimating Latent Heat (LH) as a fraction of Net surface flux

$$\text{Net flux} = R_n + \text{SH} + \text{LH}$$

$$\text{LH} = \beta \cdot (\text{Netflux} - (\overline{R_n}))$$

$$\beta = \frac{(\overline{\text{LH}})}{(\overline{\text{Htflux}})}$$

From NOC flux (v2) data, for RAPID-Argo domain:

$$\text{Net flux} = 0.82 \pm 0.17 \text{ PW}$$

$$R_n = -1.4 \pm 0.12 \text{ PW}$$

$$\beta = 0.90 \pm 0.09$$

$$\rightarrow \text{LH} = 2.0 \pm 0.27 \text{ PW}$$

Equivalent to an evap. of:

$$E = 0.8 \pm 0.1 \times 10^9 \text{ Sv}$$

NCEP2 RAPID-Argo domain annual mean latent heat flux

# Annual-mean freshwater budget: (assuming $dM/dt \sim 0$ )

$$P = E - R - \text{FWtrans}_{26.5} + \text{FWtrans}_{41} + \text{FWtrans}_{\text{Med}}$$

	FW flux ( $10^9 \text{ kgs}^{-1}$ )
26.5°N transport	$-0.022 \pm 0.08$
41.5°N transport	$+0.002 \pm 0.001$
Straits of Gibraltar throughflow	$-0.041 \pm 0.01$ (Criado-Aldeanueva <i>et al</i> , 2012)
<b>Net ocean transports</b>	<b><u><math>-0.06 \pm 0.06</math></u></b>
Runoff	$0.041 (\pm 0.02 ?)$ (Dai <i>et al</i> , 2009)
E-P	<b><u><math>-0.02 \pm 0.084</math></u></b>
E	$-0.8 \pm 0.1$
P (inferred)	<b><u><math>0.82 \pm 0.13</math></u></b>

# Annual-mean precipitation inferred from RAPID-Argo

	FW flux ( $10^9$ kgs $^{-1}$ )
26.5°N	$-0.022 \pm 0.08$
41.5°N	$+0.002 \pm 0.01$
Straits of Gibraltar	$-0.041 \pm 0.01$
<b>Net ocean transports</b>	<b><u><math>-0.06 \pm 0.08</math></u></b>
Runoff	$0.041 (\pm 0.02 ?)$
E-P	<b><u><math>-0.02 \pm 0.084</math></u></b>
E	$-0.8 \pm 0.1$
P (inferred)	<b><u><math>0.82 \pm 0.13</math></u></b>

# Relationship to near-surface salinity

On shorter timescales,  $dM_{FW}/dt$  is non zero...

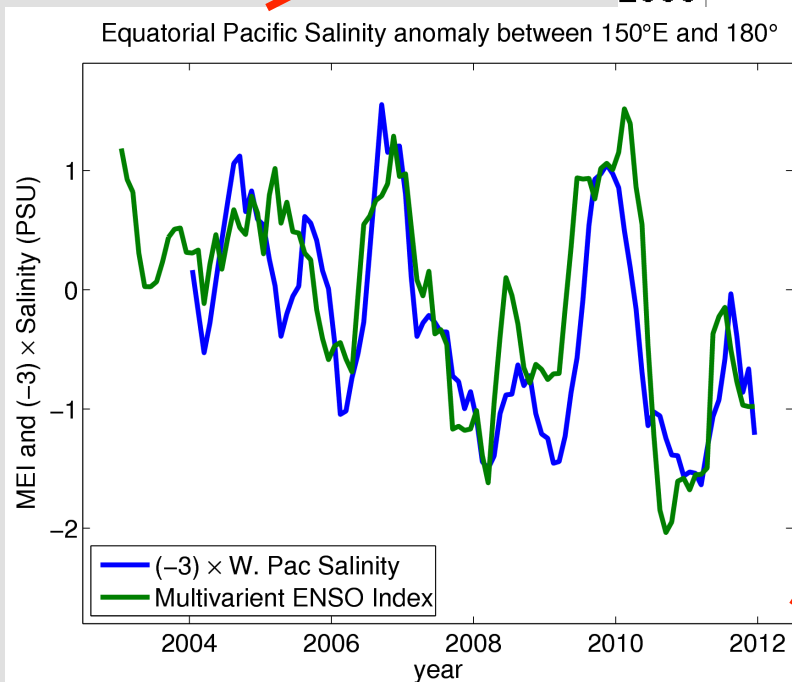

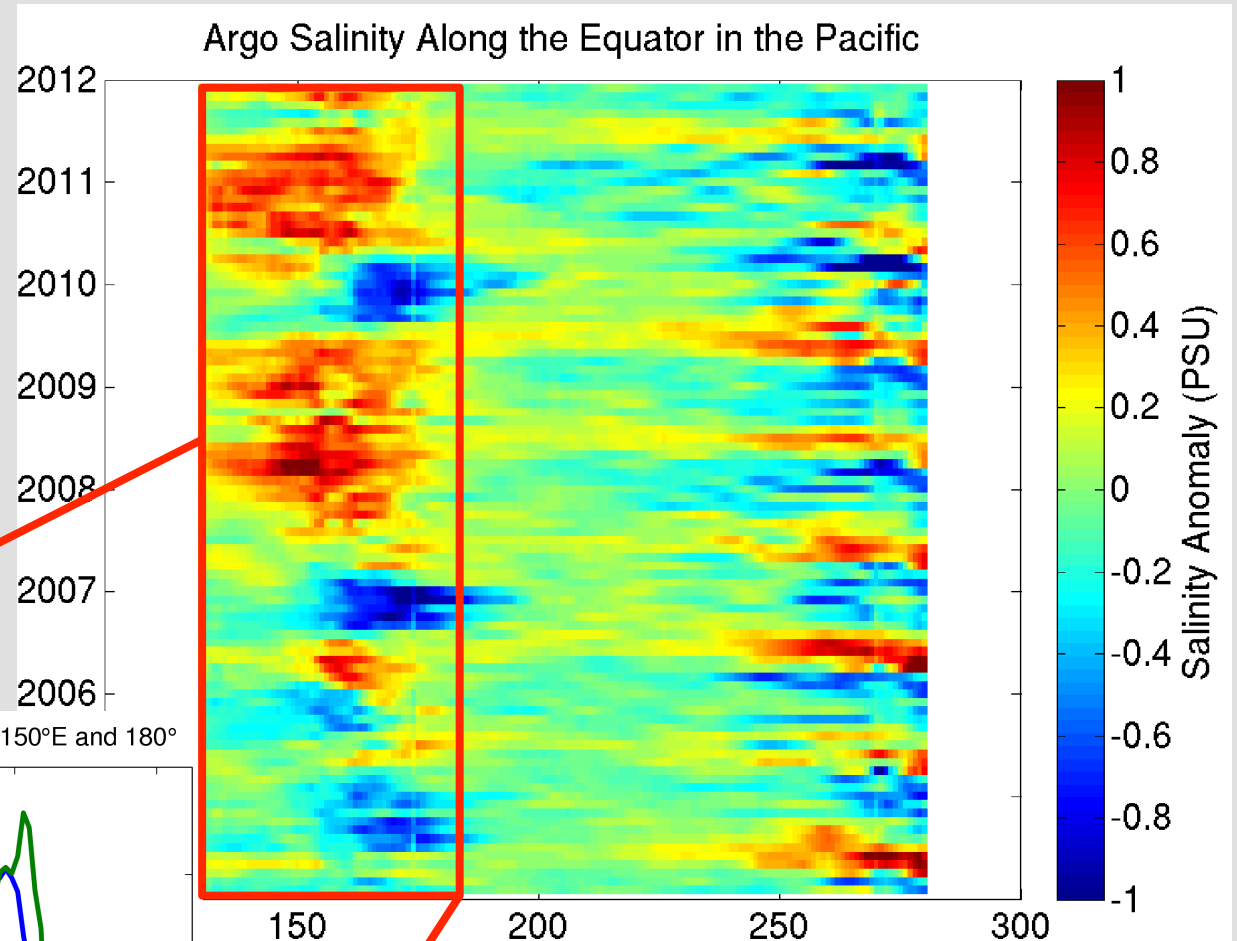

$$E - P = R + FWtrans_{26,5} - FWtrans_{41} + M + \rho \int \frac{\partial SSH}{\partial t} dA + f \left( \frac{\partial S}{\partial t} \right)$$

Estimating this relationship is the challenge!

# **FIRST LOOK AT ENSO FROM AQUARIUS**

# Argo near-surface salinity shows strong ENSO signal in the Western Pacific

Scaled salinity and MEI comparison

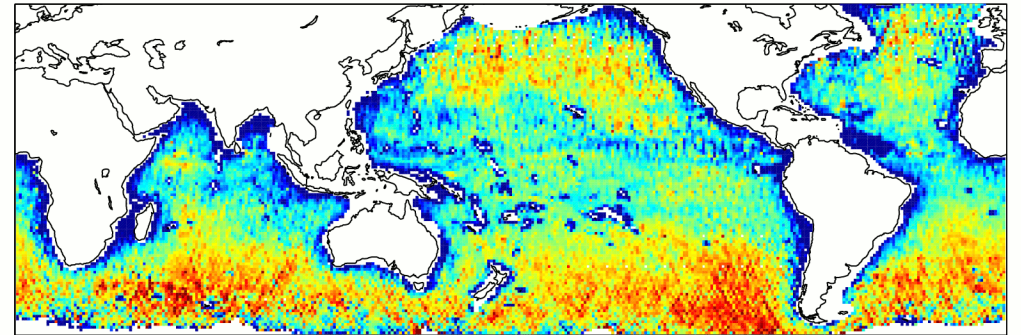

# Aquarius minus Argo mean ('05 – '08)

December, 2011

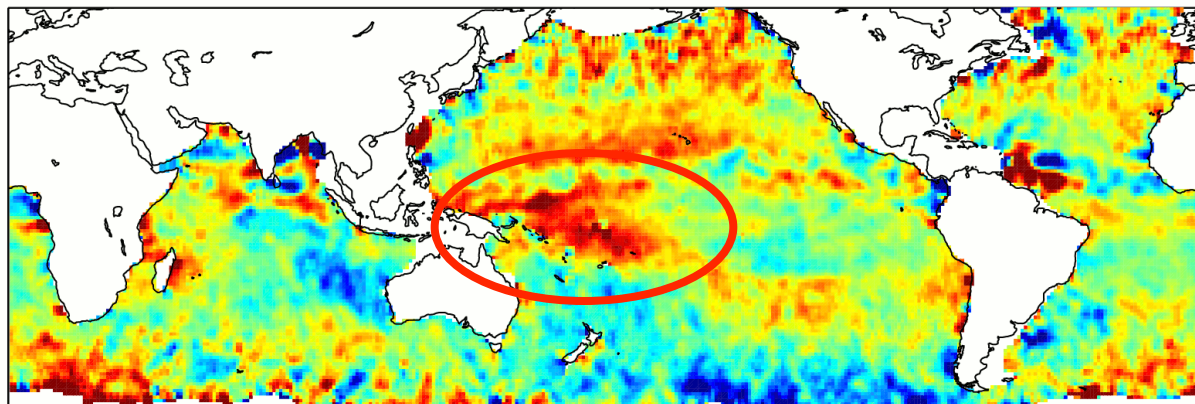

Salinity Anomaly (PSU)

# Aquarius Sept-Oct '11 minus Argo Sept-Oct '11

Salinity difference (PSU)

December, 2011

Salinity Anomaly (PSU)

“bias corrected”  
Aquarius anomaly for  
Dec. 2011

# Argo based salinity along the Equator

During the 2010 El Niño event, near surface salinity is low in the west and salinity maximum is near the center of the Pacific

During the 2010 La Niña event, near surface salinity is high in the west and salinity maximum has migrated west

# Summary

- Estimates of annual-mean  $P$  from heat and freshwater budgets are reasonable, but somewhat high.
- For sub-monthly time scales, more work required to relate salinity data to  $E-P$  to get useful estimates
- ENSO variability should be one of the biggest large-scale, climate signals visible in the Aquarius data
